

# The `homalg` project and its related packages

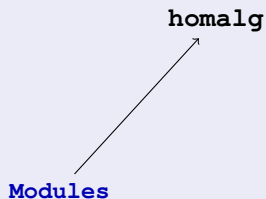

The `homalg` project authors

2007-2020

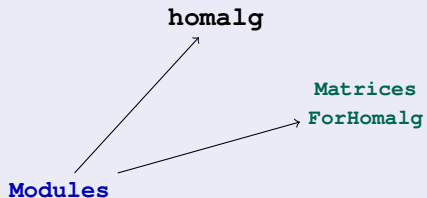

The idea: A homological algebra meta-package for computable ABELian categories

**homalg**

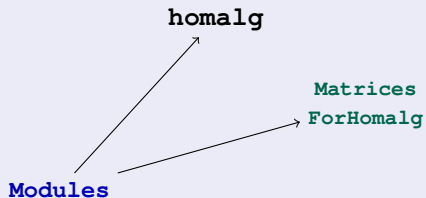

The category of finitely presented modules as the basic example of a computable ABELian category

Matrices provide the needed data structure for finitely presented modules and their morphisms

Candidates: There are several systems that could host `homalg`

Maple

MAGMA

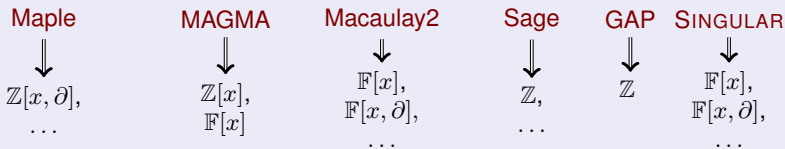

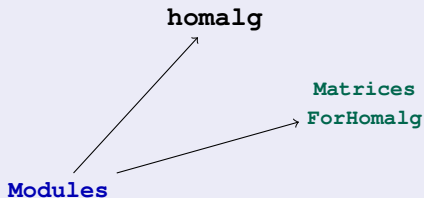

Macaulay2

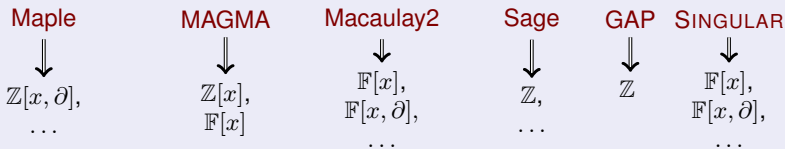

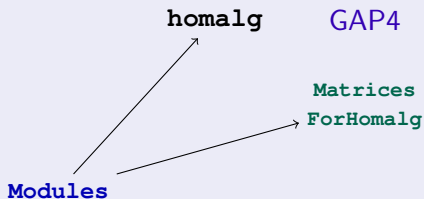

Sage

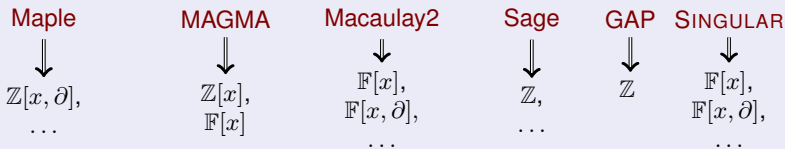

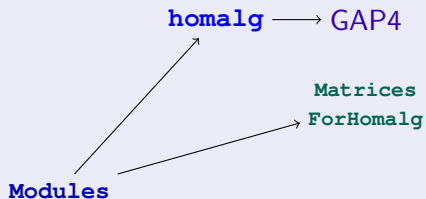

GAP

SINGULAR

Candidates: There are several systems that could host `homalg`, each supporting certain kinds of rings

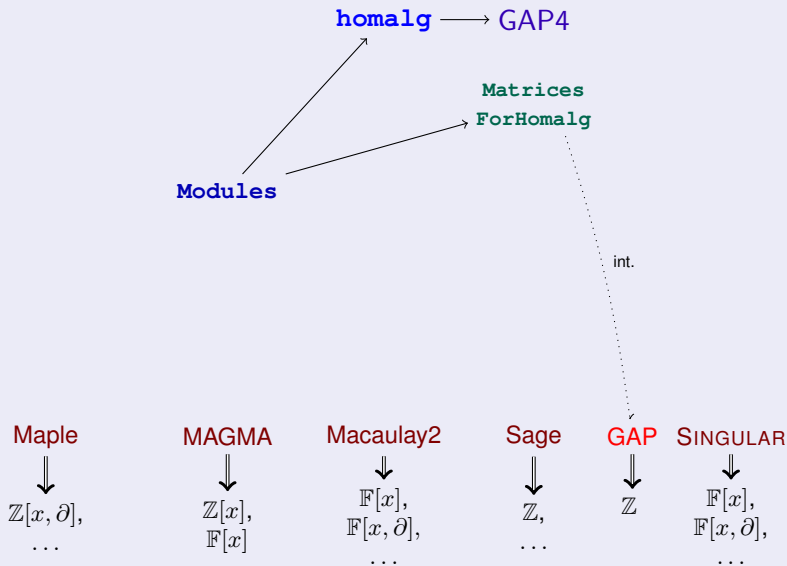

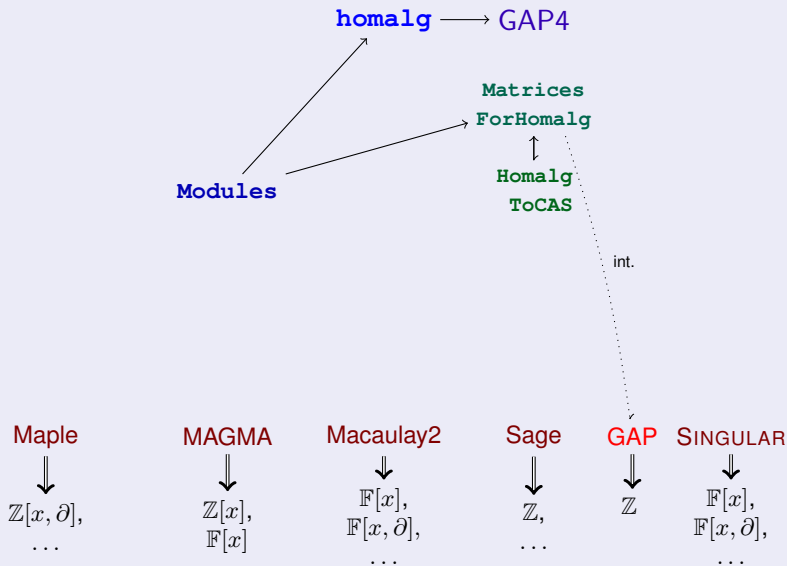

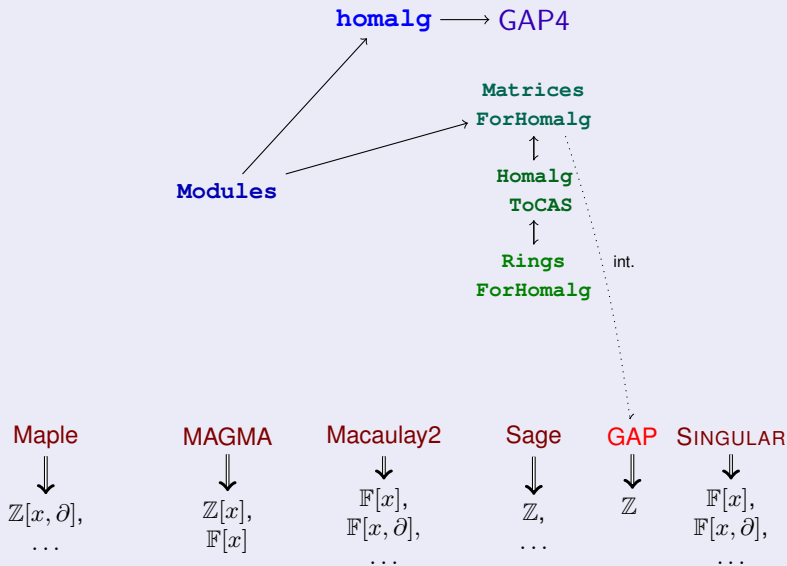

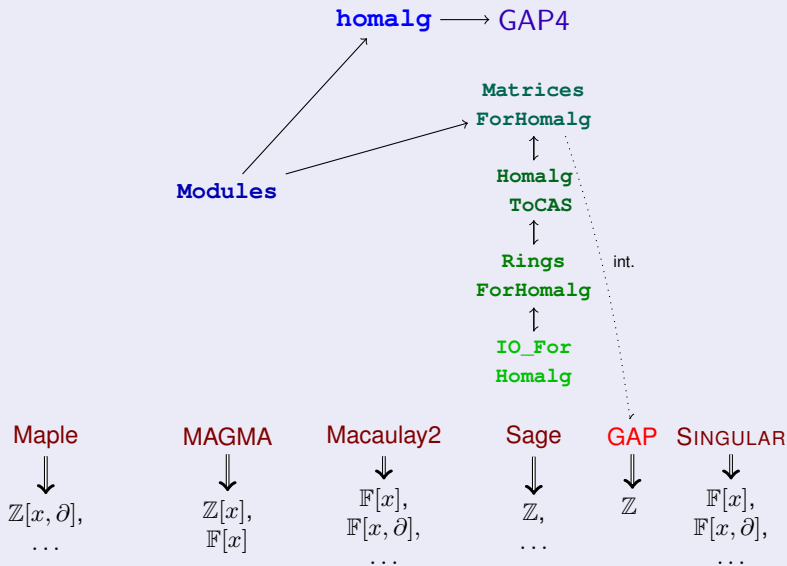

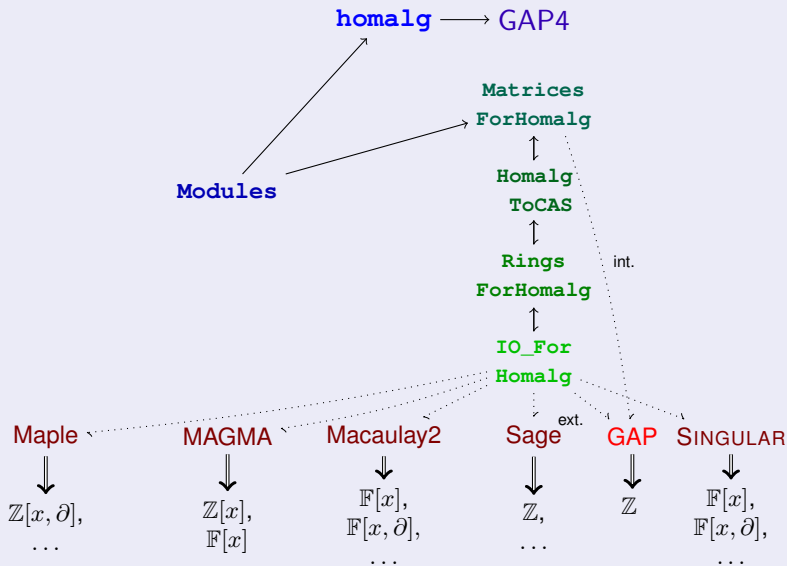

homalg: GAP “sufficiently supports” the ring of integers

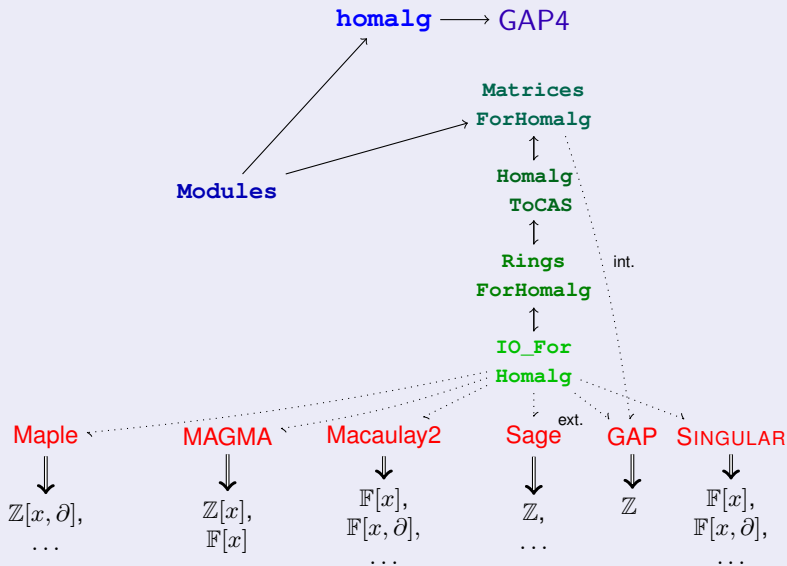

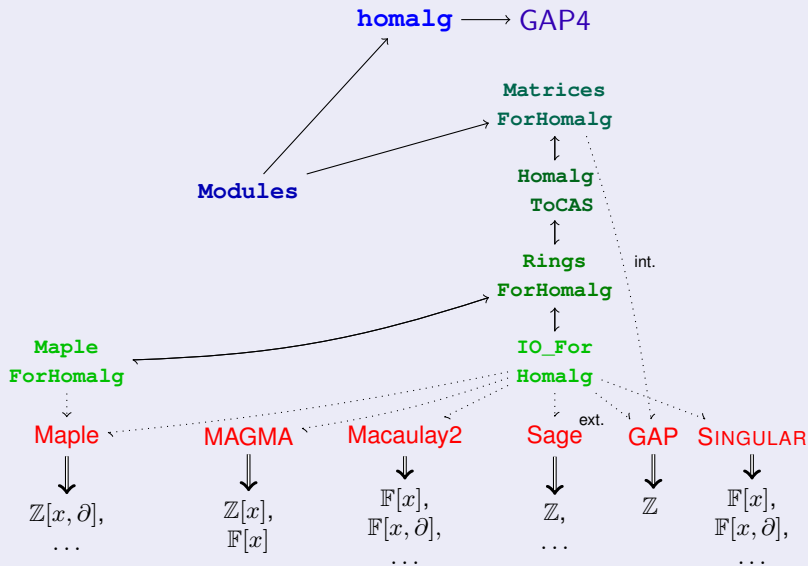

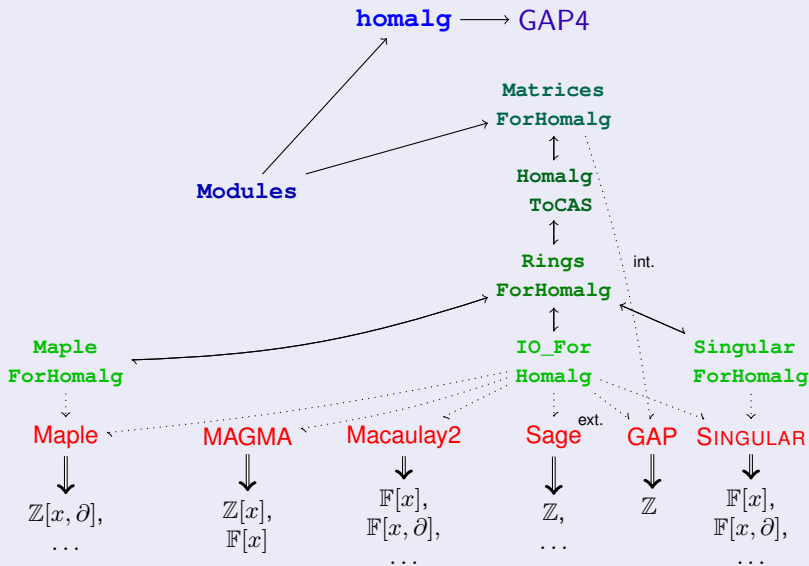

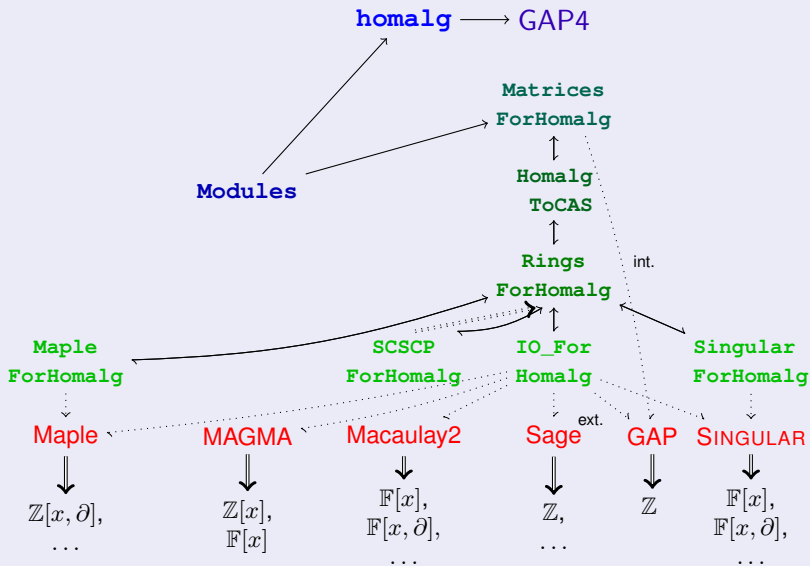

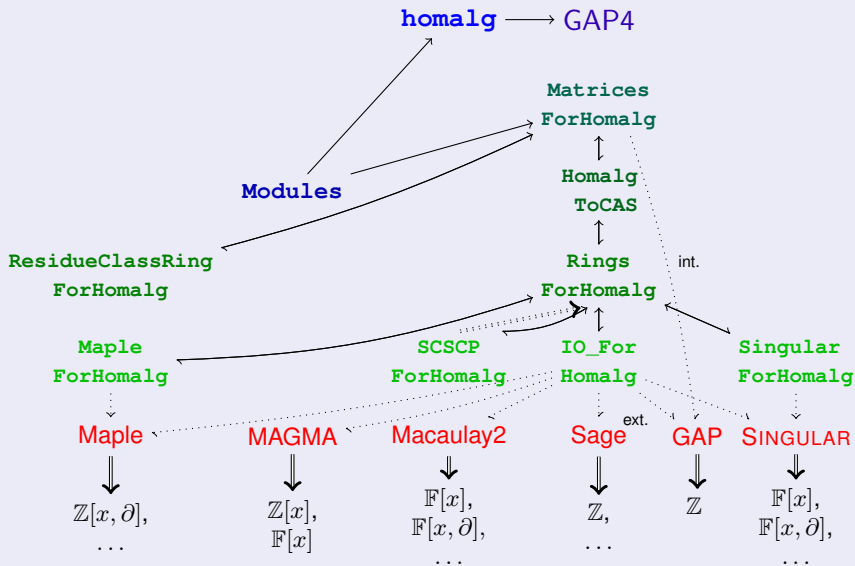

Future: Communicate with interpreters of various CASs shortcutting their command line interface.

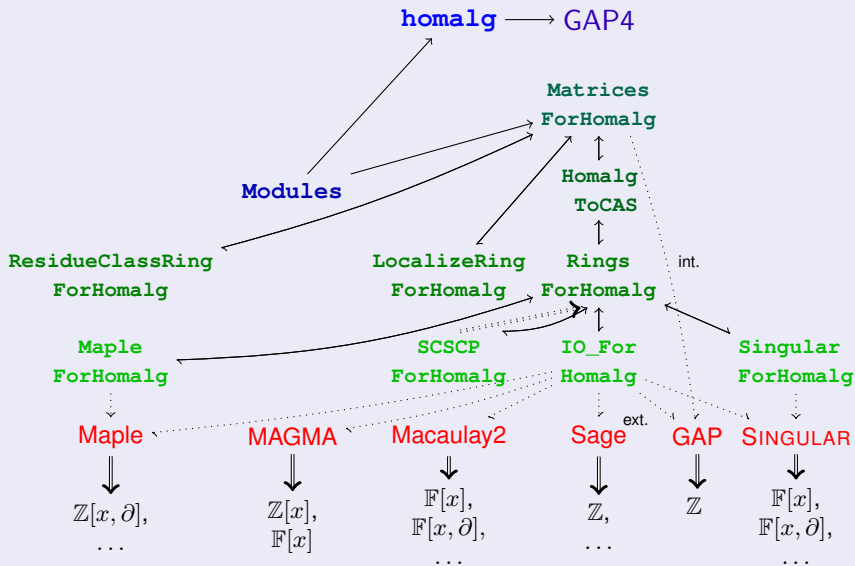

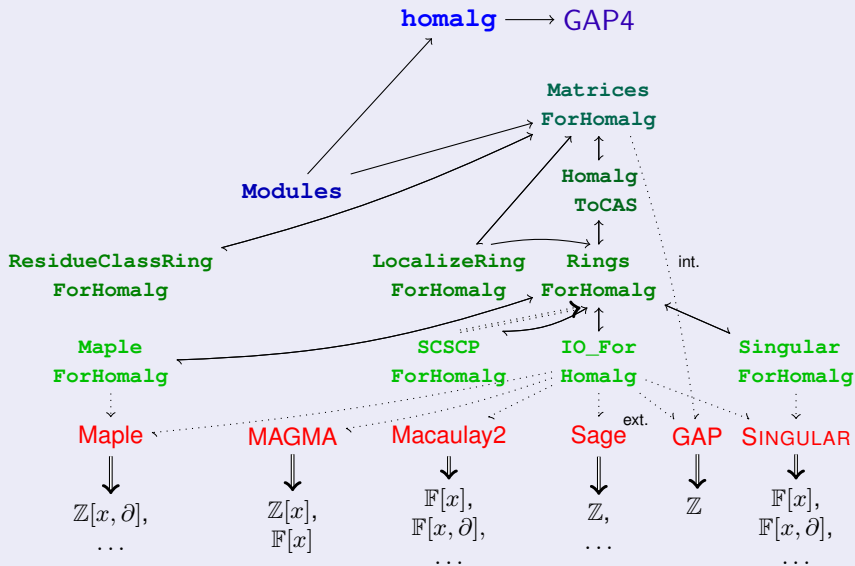

SCSCP\_ForHomalg: SCSCP can be used to reach computing engines running on local or remote machines

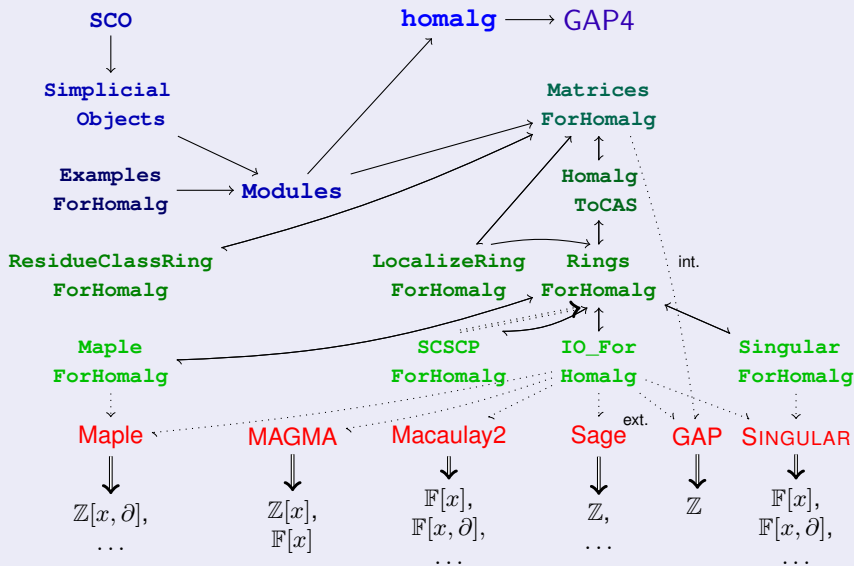

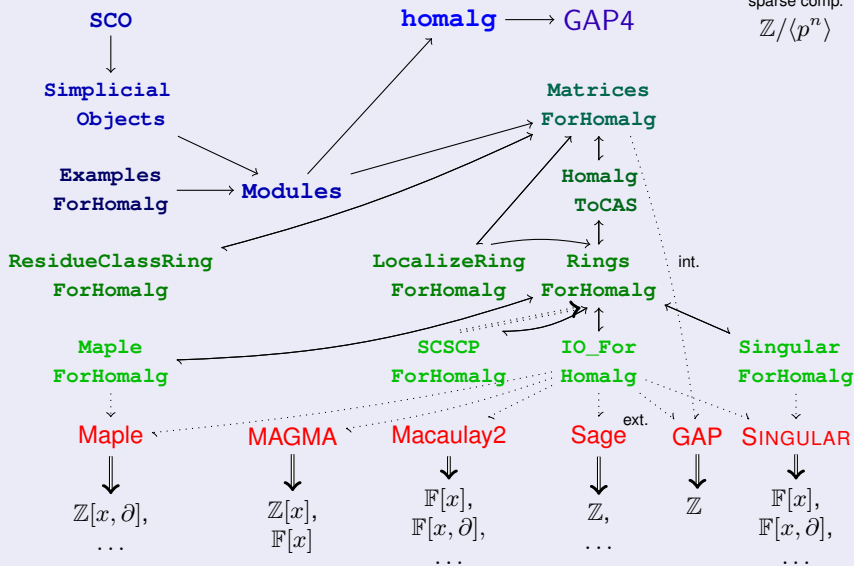

LocalizeRingForHomalg: Use MORA's algorithm in SINGULAR to localize polynomial rings at maximal ideals.

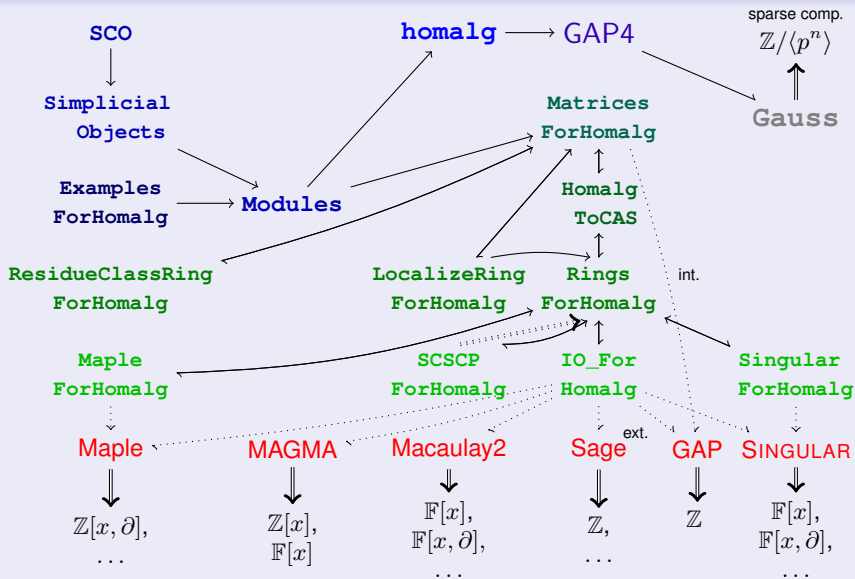

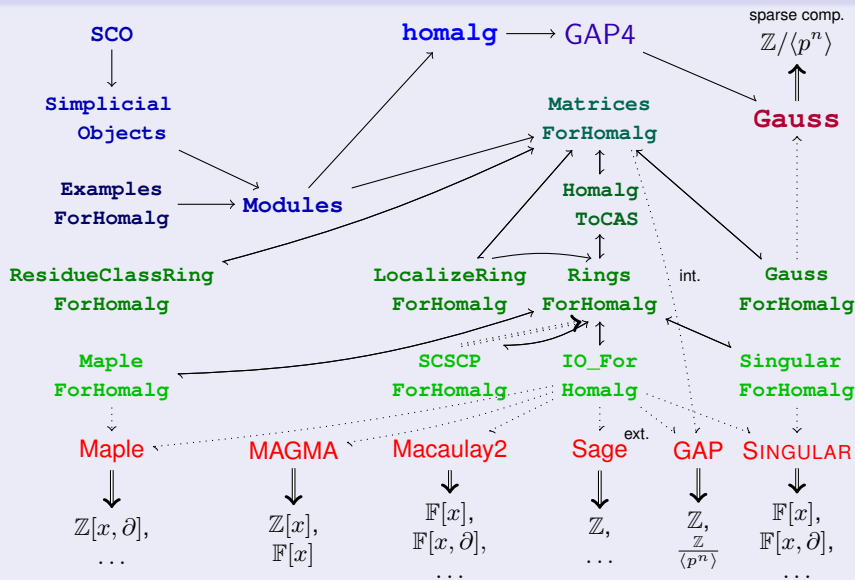

Gauss: Added missing RREF to GAP4 for **sparse** matrices over  $\mathbb{Z}/p^n\mathbb{Z}$  and  $\mathbb{Q}$

GradedRingForHomalg: Multi-graded rings serve as the data structure underlying many geometric constructions
